

## 1. Introduction.

This is the start of the introduction. The reconstruction conjecture states that the multiset of unlabeled vertex-deleted subgraphs of a graph determines the graph, provided it has at least 3 vertices. A version of the problem was first stated by Stanisław Ulam. In this paper, we show that the conjecture can be proved by elementary methods. It is only necessary to integrate the Lenkle potential of the Broglington manifold over the quantum supervacillatory measure in order to reduce the set of possible counterexamples to a small number (less than a trillion). A simple computer program that implements Pipletti's classification theorem for torsion-free Aramaic groups with symplectic socles can then finish the remaining cases.

It is possible to write text directly.

**bold** is bold. *bold-italic* is bold and italic.

Line of text, just another line of text, and another line of text.

## 2. Methods

This section is for the description of methods, which were used in this manuscript. A simple computer program that allows produce dvi is here needed.
